SANDIA CORPORATION BIBLIOGRAPHY

IMPACT PHYSICS

by

Robert Graham
Physical Research Department
Sandia Corporation

December 1958

ABSTRACT

This bibliography consists of a rather complete collection of references and abstracts on the subjects of: (1) plastic wave propagation in bounded solids; (2) behavior of metals under explosive conditions; (3) dynamic photoelasticity; (4) penetration phenomena. Other topics covered in less detail are: (5) behavior of material at high strain rates; (6) lateral impact; (7) impact measurement devices.

General references at the beginning of the bibliography cite articles or books which cover the field of impact. An author index and a chronological listing of articles within a particular topic are included.

PREFACE

The Physical Research Department at Sandia Corporation has encountered many impact problems in its past and current activities. In order to become familiar with past work in this field, a systematic search and study of the literature was undertaken. This bibliography is the result of the literature search and is being published since comparison with other bibliographies shows it to be more complete in certain areas.

The subject of wave propagation is an important consideration in most impact problems but it was decided not to search the literature for articles dealing with wave propagation, as such, since this extensive field is the subject of several recent survey articles and books.[1, 2, 3, 6, 7, 8]*

The bibliography in its final form deals with wave propagation as it applies to specific areas of interest in impact problems. The references have been assembled into groups according to the main topic of the reference. The major subjects included in the bibliography are:

1. Plastic Wave Propagation in Bounded Solids
2. Behavior of Metals Under Explosive Conditions
3. Dynamic Photoelasticity and Related Topics
4. Penetration Phenomena

All of the references listed under these subjects are articles which are technically related and which normally follow the same general trend of thought in the literature. These subjects are felt to be well developed in the bibliography. That is, the references listed can be considered as representing a high percentage of the total references on this subject. To obtain this extensive coverage a search was made of the indexes of well known applied mechanics and physics publications. The articles listed in these indexes were then obtained and the references in each article were added to the bibliography. This new list of references was searched for more references, this method being continued until the list of references given by the various articles converged.

The subjects listed below are also included in this bibliography but do not necessarily represent extensive coverage of the subject:

5. Behavior of Materials at High-Strain Rates
6. Impact Measurement Devices
7. Lateral Impact-Beams and Plates
8. Miscellaneous

The general references listed at the beginning of the bibliography are a group of articles or books which cover the field of impact rather completely. No attempt has been made to duplicate the bibliographies given in these references.

---

*Superscripts refer to reference numbers in the bibliography.

To improve the usefulness of the bibliography, a complete author index has been prepared along with a chronological listing of the references within a particular subject. The chronological listing is particularly helpful in giving the proper perspective to the various references.

The abstracts included are either the author's abstracts or short reviews made by this author.

To obtain current information on activities throughout the nation, an extensive trip has been made to the various centers of activity in this field. The observations made on this trip have been very enlightening and have served to give information which would not appear in the literature for some time. A report on this trip will be published in a Sandia Corporation Technical Memorandum.

The author hopes that users of the bibliography will call attention to errors or omissions.

The author would like to express appreciation to A. F. Beck who suggested this work, and Dr. S. E. Whitcomb who made many helpful suggestions.

Bibliography

1001 Taylor G I and Whiffin A C
THE USE OF FLAT-ENDED PROJECTILES FOR DETERMINING DYNAMIC YIELD STRESS
Proceedings of the Royal Society of London
1948, Series A, Vol. 194, p. 289.

The deformation of a flat-ended projectile, due to being fired at high velocity against a steel plate, is used as a measure of the dynamic yield stress of the projectile. In Part I the theory of the method is presented. Results of experimental tests are shown in Part II. Satisfactory results obtained for velocity of impacts from 400 to 2500 ft/sec.

1002 Johnson J E, Wood D S and Clark D S
DYNAMIC STRESS-STRAIN RELATIONS FOR ANNEALED 2S ALUMINUM UNDER COMPRESSIVE IMPACT
Journal of Applied Mechanics, Trans. ASME
1953, Vol. 75, pp. 523-529.

This paper presents the results of an experimental study of the dynamic stress-strain relations for annealed 2S Aluminum. Methods of obtaining data are presented. The technique used in analyzing the data involves the use of plastic and elastic stress-wave propagation.

Impact velocities to a maximum of about 150 fps.

1003 Von Karman T and Duwez P
THE PROPAGATION OF PLASTIC DEFORMATION IN SOLIDS
Journal of Applied Physics
1950, Vol. 21, pp. 987-994.

The stress wave caused by longitudinal impact on a cylindrical bar is analyzed for the case where impact velocity is large enough to produce plastic strain. The concept of a critical velocity is presented. An experimental investigation is performed which substantiates the theoretical presentation.

1004 Clark D S and Datwyler G
STRESS-STRAIN RELATIONS UNDER TENSION IMPACT LOADING
Proceedings ASTM
1938, Vol. 38, Part II, p. 98.

Force elongation curves are obtained for several materials for an impact velocity of 11 ft/sec. It is concluded that yield forces under dynamic conditions are higher than under static conditions.

1005 Clark D S and Duwez P E
DISCUSSION OF THE FORCES ACTING IN TENSION IMPACT TESTS OF METAL
Journal of Applied Mechanics, Trans. ASME
1948, Vol. 70, p. 243.

A method is described for measuring the forces acting on a specimen during a tension impact test. Plastic wave propagation theory is used to interpret the results obtained. Impact velocities to a maximum of 200 ft/sec. Very good article on interpretation of force-time curves obtained from such tests.

1006 Plass H J
A COMPARISON OF PLASTIC LONGITUDINAL WAVE THEORIES FOR STRAIGHT RODS
University of Texas, Defense Research Lab. N. 327, CF2009.

1007 Lee E H and Tupper S J
ANALYSIS OF PLASTIC DEFORMATION IN A STEEL CYLINDER STRIKING A RIGID TARGET
Journal of Applied Mechanics, Trans. ASME
1954, Vol. 76, p 63.

The G. I. Taylor dynamic compression test (article 1001) is used to determine the entire strain distribution for a test cylinder of nickel-chrome steel. In the interpretation of results, interest is concentrated on the plastic and elastic wave fronts which emanate from the surface of contact. The theory of the propagation of plastic waves is presented. This is a fundamental article in relation to impacts large enough to cause plastic deformation. Impact velocities to about 1500 fps.

1008 Lee E H and Wolf H
PLASTIC-WAVE PROPAGATION EFFECTS IN HIGH SPEED TESTING
Journal of Applied Mechanics, Trans. ASME
1951, Vol. 73, p. 379.

This article discusses how a material test carried out at high speed may be markedly influenced by plastic-wave

propagation effects. The range of speed is determined which permits satisfactory test interpretation without the need for detailed plastic-wave analysis.

Fundamental article on the interpretation of high speed material tests.

1009 Habib E T
A METHOD OF MAKING HIGH-SPEED COMPRESSION TESTS ON SMALL COPPER CYLINDERS
Journal of Applied Mechanics, Trans. ASME
1948, Vol. 70, p. 248
Discussion Journal of Applied Mechanics, 1949, Vol. 71, p. 98.

High-speed compression tests are performed on small copper cylinders by subjecting them to the impact of a piston fired from a pneumatic gun. Experimental techniques are discussed and results of the tests are shown as energy absorbed versus deformation. The complication due to plastic strain waves is mentioned.

Velocity of impact 25-200 fps.

1010 White M P and Griffis LeVan
THE PROPAGATION OF PLASTICITY IN UNIAXIAL COMPRESSION
Journal of Applied Mechanics, Trans. ASME
1948, Vol. 70, p. 256.
Discussion Journal of Applied Mechanics, 1949, Vol. 71, p. 219.

A theoretical investigation of the mechanism of uniaxial compression impact on elastic-plastic materials is described. It is concluded that four different modes of behavior can occur, depending on the impact velocity.

1011 Sternglass E J and Stuart D A
AN EXPERIMENTAL STUDY OF THE PROPAGATION OF TRANSIENT LONGITUDINAL DEFORMATIONS IN ELASTOPLASTIC MEDIA
Journal of Applied Mechanics, Trans. ASME
1953, Vol. 75, pp. 427-434.

An experimental study is presented which is concerned with confirming the theory of the propagation of plastic waves. It is concluded that the velocity of propagation of the wave front is that of the elastic wave which is not in agreement with theory as proposed by Von Karman and Taylor.

1012 Malvern L E
THE PROPAGATION OF LONGITUDINAL WAVES OF PLASTIC DEFORMATION IN A BAR OF MATERIAL EXHIBITING A STRAIN-RATE EFFECT
Journal of Applied Mechanics, Trans. ASME

1951, Vol. 73, pp. 203-208
Discussion Journal of Applied Mechanics, 1951, Vol. 73, pp. 428-429.

The theory of propagation of plastic longitudinal waves is extended to include the strain rate effect on the stress-strain curve.
See also 1052. Bibliography contains 30 references.

1014 White M P
ON THE IMPACT BEHAVIOR OF A MATERIAL WITH A YIELD POINT
Journal of Applied Mechanics, Trans. ASME
1949, Vol. 71, pp. 39-52
Discussion Journal of Applied Mechanics, 1949, Vol. 71, pp. 318-319.

A very complete analysis is made of impact behavior of materials with a yield point. The theory of plastic wave propagation and the combination of plastic and elastic waves is presented very clearly.

1015 White M P and Griffis LeVan
THE PERMANENT STRAIN IN A UNIFORM BAR DUE TO LONGITUDINAL IMPACT
Journal of Applied Mechanics, Trans. ASME
1947, Vol. 69, pp. A-337-343.

A method is presented for giving the final distribution of strains in a uniform bar subjected to a plastic impact. The wave propagation theories are used in the development. The presentation is very basic from the standpoint of interpretation of impact stresses and strain in cylindrical specimens.

1020 Campbell J D
AN INVESTIGATION OF THE PLASTIC BEHAVIOR OF METAL RODS SUBJECTED TO LONGITUDINAL IMPACT
Journal of Mechanics and Physics of Solids
1953, Vol. 1, pp. 113-123.

A dynamic stress-strain relation is obtained for an aluminum alloy. An SR-4 type strain gage is mounted on the specimen. The specimen is in the form of a long rod. Successively larger impacts are imparted to the specimen to obtain a stress-strain curve. Impact is applied to a steel rod then transmitted into the specimen. The effect of the steel rod is to increase the applied stress and also separates the flexual and longitudinal components due to differences in velocity of propagation.

ON THE RELATION AMONG STRESS, STRAIN, AND STRAIN RATE IN COPPER WIRES SUBMITTED TO LONGITUDINAL IMPACT
Proceedings Society for Experimental Stress Analysis
1956, Vol. XIV, No. 1, pp. 55-70.

A series of exploratory tests of tensile impact on copper wires is presented to show that the elastic component of a stress wave moves at a constant velocity regardless of the amount of plastic deformation. Method consists of dropping weight on copper wire. Bright tin spots on wire are photographed with high-speed photography to observe motion of the stress waves.

THEORETICAL AND EXPERIMENTAL STUDIES OF PLASTIC WAVE PROPAGATION IN LONGITUDINAL RODS SUBJECT TO IMPACT
Johns Hopkins University, Institute for Cooperative Research
Contract No. DA-36-034-ORD-2366, 1956.

A new method employing diffraction gratings of very short length will be utilized to study propagated plastic wave fronts of large magnitude. Unloading waves, reflected waves from fixed and free ends. Dynamic determination of Poisson's ratio.

1064 Rubin R J
PROPAGATION OF LONGITUDINAL DEFORMATION WAVES IN A PRESTRESSED ROD OF MATERIAL EXHIBITING A STRAIN-RATE EFFECT
Journal of Applied Physics
1954, Vol. 25, pp. 528-536.

The longitudinal propagation of stresses above the yield stress in a material exhibiting a strain-rate effect is studied analytically. Mathematical expressions are developed which describe the wave propagation. The system analyzed is a semi-infinite rod subjected to end impact.

This article is referred to by many investigators and several extensive experiments are being conducted to verify this theory.

1065 Campbell J D
THE YIELD OF MILD STEEL UNDER IMPACT LOADING
Journal of Mechanics and Physics of Solids
1954, Vol. 3, pp. 54-62.

In an extension of work reported in article 1020 the dynamic stress-strain curves of mild steel are obtained. The apparatus is adapted so that the steel rod which transmits the stress to the specimen is larger than the specimen. This increases the stress transmitted into the specimen. The strain gage is attached to the specimen.

1066 Campbell J D and Maiden C J
THE EFFECT OF IMPACT LOADING ON THE STATIC YIELD STRENGTH OF A MEDIUM CARBON STEEL
Journal of Mechanics and Physics of Solids
1957, Vol. 6, pp. 53-61.

Although the results of this investigation are not of particular interest the experimental technique is interesting. A similar test setup is used as in articles 1020, 1065. Stress magnitude is amplified by transmitting the impact through steel rods of two cross-section changes. This amplifies the stress about two times. Strain gages are attached to the anvil bar.

ENGRAVEMENT OF TRANSIENT STRESS WAVE PARTICLE VELOCITIES
Journal of Applied Physics
1953, Vol. 24, pp 462-469.

A simple and unique technique is described for determining the particle velocity of a material subjected to high-speed loading. The force is applied to a plate that has a pellet attached on the opposite side. The propagation of the wave through the plate and pellet causes the pellet to indent the surface of the plate. Average particle velocity can be determined by measuring the depth of penetration.

TRANSIENT WAVES THROUGH STEEL PRODUCED BY IMPULSIVE LOADING
Paper presented at meeting of American Physical Society
Berkeley, California, December 27-29, 1951
Abstract in Physical Review, 1952, Vol. 85, p. 769.

The transient behavior of a thick circular plate deforming under explosive attack has been investigated. An experimental technique, based upon the principle of the optical lever has been used to measure surface oscillations as small as 10μ in amplitude. Measured particle velocities determined by this method indicate the presence of elastic and plastic waves.

SOME TENSILE FRACTURES GENERATED IN METALS BY IMPULSIVE COMPRESSIONAL LOADING
Paper presented at meeting of American Physical Society
Berkeley, California, December 27-29, 1951
Abstract in Physical Review, Vol. 85, p. 768.

One aspect of the part that high intensity stress waves play in the fracturing of metal cylinders subjected to internal explosive loading has been studied. It has been found that tensile type fractures will result from the interference of reflected tensile stress waves whenever the resulting tensile stress exceeds the critical normal fracture stress of the material _____. Stress wave velocities have been measured for low-carbon steel, brass, copper, lead and aluminum alloys from the geometry of fracture. These velocities are in reasonable agreement with accepted values for the velocities of dilatational waves in these metals.

SHOCK WAVES IN ELASTIC AND ELASTIC-PLASTIC MEDIA
Kungl. Fortifikations for valtningen Befästningsbyran
Rappart 109-12, 141 pp. 1956. Library of Congress P. B. 126210.

Report gives interesting review of experiments on the propagation of elastic, plastic and shock waves produced by impact and by the detonation of explosive charges. The theory of wave propagation is discussed and the propagation of spherically divergent stress-waves is treated in detail. Tables of numerical values of dynamic stress-strain results for metals and other solids are presented and the fractures produced by the reflection of intense stress waves at the free boundaries of a specimen, are described and discussed. The bibliography contains 71 references in the field, most of which are recent. (Abstract as given in Applied Mechanics Review).

DEFORMATION OF AN EXPLOSIVELY LOADED ALUMINUM SINGLE CRYSTAL
Journal of Applied Physics
1955, Vol. 26, pp. 1315-1318.

A hollow cylindrical single crystal of pure aluminum was deformed by detonating an explosive charge that had been placed axially within the crystal. The approximate strain rate achieved was 10^5 sec^{-1}. The object of the test was to relate the pattern of deformation to the stresses set up by the explosive and the crystallographic axes of the crystal. The reaction of the cylinder was markedly different from the reaction which would be exhibited by a similarly shaped cylinder of polycrystalline material. The deformation was nonuniform with both the fracturing and the plastic flow exhibiting a twofold symmetry that could be unambiguously related to the orientation of stress with respect to the crystallographic axes and their associated slip systems. (Author's abstract)

DYNAMIC DETERMINATION OF THE COMPRESSIBILITY OF METALS
Journal of Applied Physics
1955, Vol. 26, pp. 1472-1479.

Equation of state data for Duralumin in the pressure range from 0.1 to 0.3 megabar have been determined dynamically by measuring shock and free surface velocity electrically in a plate of 24 ST Duralumin that has been stressed by a high explosive detonation. A theory is presented which allows comparison with data obtained by other experimenters, and which yields the relationship

between pressure and compression either at constant entropy or constant temperature. The empirical form chosen for the equation of state ($p = a\mu + \beta\mu^2$) expresses the pressure as a quadratic function of the compression. Experimental techniques are described in detail. Five points are given for the equation of state of Duralumin in the pressure range from approximately 0.15 megabar to 0.33 megabars. Some data are also presented for cadmium and steel. (Authors' abstract)

APPLICATION OF THE ENGRAVEMENT METHOD TO THE STUDY OF PARTICLE VELOCITY DISTRIBUTION IN EXPLOSIVELY LOADED CYLINDERS
Journal of Applied Physics
1955, Vol 26, pp. 1431-1435.

Application of the engravement method to the study of particle velocity distribution in the wall of a thick-walled metal cylinder internally loaded with an explosive charge is described. Tests were conducted with this method on modified cylinders of annealed low-carbon steel and of brass. Even though each of the modified cylinders broke into a number of fragments, the engravements were well enough preserved to furnish considerable data. Many measurements were obtained from each cylinder by using a large number of pellets of several thicknesses. Particle velocity data were obtained to within 7/16 inch from the metal explosive interface. Temporal particle velocity distribution curves are presented for each of the cylinders. (Author's abstract)

1148 Minshall S
PROPERTIES OF ELASTIC AND PLASTIC WAVES DETERMINED BY PIN CONTACTORS AND CRYSTALS
Journal of Applied Physics
1955, Vol. 26, pp. 463-469.

Experimental techniques are described by which one can observe the separation of a shock wave in a metal into an elastic wave and a slower plastic wave. The plastic-wave velocity was about 15 percent less in steel and 10 percent less in tungsten than the elastic-wave velocity, at pressures imparted by Composition B explosive. Elastic-wave velocities were the same, within experimental error, as the measured sound velocities. The pressure in the elastic wave in SAE 1020 steel, deduced from the material and wave velocities, is independent of the plastic-wave pressure within experimental accuracy, and is about 12 kilobars. SAE 1040 steel, however, does not exhibit a single characteristic elastic-wave pressure. The pressure initially is about 6 kilobars and increases to about 12 kilobars before the arrival of the plastic wave. (Author's abstract)

ELASTIC DESCRIPTION OF A HIGH-AMPLITUDE SPHERICAL PULSE IN STEEL
Journal of Applied Physics
1955, Vol. 26, pp. 69-74.

Extensive calculations have been performed with an electronic calculator to evaluate a problem in elasticity that simulates the effect of a cylindrical charge of high explosive detonated in intimate contact with a steel plate. The general method of calculation has been described in detail. Although elastic theory has been extrapolated into a regime where it is known not to apply, insight of a valuable general nature has been obtained on the nature of the negative component of the pulse. (Author's abstract)

1155 Kumar S and Davids N
BASIC THEORY OF SCABBING-ELASTO-PLASTIC WAVE PROPAGATION
Interim Technical Report No. 10, Pennsylvania State University.

Semi-graphical approaches to the propagation of stress pulses in bars created by impacts is presented. This report consists of two main parts, viz., "Stress Jump Approach" and the "Strain Contour Approach." In the first part, after a brief discussion and development of the theory of plastic wave propagation, solutions of a number of problems with various boundary conditions for rectangular and triangular pulses of both long and short duration, are presented. An idealized stress-strain diagram for 14 ST-4 Aluminum alloy obtained in our laboratory has been used for most of the above cases. In the second part, first the theory of contour propagation in the X-T plane is developed and a set of rules that govern their geometrical patterns are presented. Then solutions are provided for most cases of reflections and interactions of the strain and velocity contours that are considered necessary for solving any given problem. (Authors' abstract)

1156 Dewey J, Breidenbach H I and Gehring J W
SOME OBSERVATIONS OF ELASTIC PROPERTIES OF SOLIDS UNDER EXPLOSIVE LOADING
Ballistic Research Laboratories, Report No. 931.

The strains and shock fronts in a magnesium alloy subjected to a contact detonation have been determined from flash radiographs. From these the stresses and stress-strain ratios for the compressional and shearing strains at the shock fronts have been computed, using finite strain theory. The compressional stress-strain ratio exceeds the infinitesimal and increases rapidly with strain. The shearing stress-strain ratio is considerably lower than the infinitesimal and about that predicted from Murnaghan's second order theory, $\mu - p$. Much less complete observations on plate glass and Catalin 61-893 are reported and reduced. Observations on heavier materials give subsonic shock velocities under very high stresses. In all materials except glass the compression front is markedly curved, indicating a rapid decay of shock strength. (Authors' abstract)

MULTIPLE SCABBING IN MATERIALS
Interim Technical Report No. 4, OOR Project TB2-0001 (1253), Pennsylvania State University.

This report discusses first, scabbing and multiple scabbing from a phenomenological point of view, then past experiments on scabbing with critical comments. It then suggests new types of experiments and the use of an

inverse approach which could yield information on pulse shapes and some of the dynamic properties of the material. The relationships among these quantities have been determined graphically. (Authors' abstract)

1158 Davids N and Kumar S
THE BASIC THEORY OF SCABBING IN MATERIALS WITH TWO SOLIDS IN CONTACT, PART I, ELASTIC THEORY
Interim Technical Report No. 1, OOR Project TB2-0001 (1253), Pennsylvania State University.

Basic relationships for scab formation in a solid are developed from the point of view of elastic materials. Relationships giving the thickness of scabs are obtained for semi-infinite plates and thin rods on the basis of normally-incident pressure pulses of arbitrary form. The effect of a backing medium has been expressed in terms of impedance matching relations between the two media, and these used to determine quantitatively the reduction in stress. Criteria for required thicknesses are developed on the basis of momentum considerations. A preliminary treatment is included for spherically-diverging waves arising from a point explosion in a semi-infinite medium. Some available data are made use of in a discussion for the purpose of evaluating time constants of typical pressure pulses used in the report. (Authors' abstract)

1159 Davids N
STRESS WAVES OF PENETRATION IN PLATES
Interim Technical Report No. 12, OOR Project No. TB2-0001 (1253) Pennsylvania State University.

Scabbing effects in plates may be analyzed theoretically by assuming elastic stress-waves excited periodically at a point-source on its boundary. The usual classical results are inaccurate since, first, the damaging wave is the one penetrating through the plate rather than propagating along it, and second, the dimensions of the plate in practical applications are just of the order of a wavelength. A more precise boundary-value problem is worked out and resulting axial stress-wave distributions for aluminum plates are given. (Author's abstract)

1160 Kumar S
SCABBING IN BARS AND PLATES - FURTHER STUDIES
Interim Technical Report No. 13, OOR Project TB2-0001(1253) Pennsylvania State University.

Scabbing, a fracture phenomenon in materials, due to stress reversal of strong dynamic loads, is first discussed here from a phenomenological point of view. Then an elastic analysis for determining scab lengths both in bars and plates under plane stress and plane strain is presented. As a further refinement, after explaining briefly and applying the basic theory of

elastoplastic wave propagation in solids, a study is made of scabbing possibilities in bars by semi-graphical methods, and also the basis for the elasto-plastic analysis of scabbing in plates. Implications of both the elastic and elastoplastic analyses are compared. Idealized stress-strain relations for 14ST-4 Aluminum, obtained in our laboratory, have been used. (Author's abstract)

1161 Duvall G E
PRESSURE-VOLUME RELATIONS IN SOLIDS
American Journal of Physics
1958, Vol. 26, pp. 235-238.

An equation of state of the form $P(V) = f(V) + Tg(V)$, which is useful for condensed matter, is proposed for the illustration of thermodynamic principles. Pressure-volume relations for adiabatic and shock compressions are derived with the assumption that specific heat at constant volume is independent of temperature. These derived relations are illustrated for a "Murnaghan" equation of state, and constants of this equation for several metals are tabulated. (Author's abstract)

HUGONIOT EQUATION OF STATE OF ALUMINUM AND STEEL FROM OBLIQUE SHOCK MEASUREMENT
Stanford Research Institute, Poulter Laboratories, Lab. Technical Report 018-57, December 1957.

A new method for determining the Hugoniot equation of state of solids has been developed. This method uses an oblique shock in a wedge-shaped specimen, cut so that the oblique shock is incident at an angle close to normal over the wedge face. The oblique shock is produced by a slab of explosive, lying on top of the wedge and line-initiated, providing essentially a two-dimensional shock. Simultaneous measurement of shock and free-surface velocities down the wedge face provides the data for calculation of the Hugoniot pressure and density over a wide range on a single shot. In aluminum a pressure range exceeding 2:1 may be observed on a single shot. (Authors' Summary)

THE DYNAMIC COMPRESSIBILITY AND THE EQUATION OF STATE FOR IRON AT HIGH PRESSURES
Zhur. Eksper. i Teoret. Fiz. 34:874-85, No. 4, April 1958.

The paper describes two methods for measuring the dynamic compressibility of substances. These methods are based on determining the kinematic parameters of shock waves (propagation velocity and the mass velocity of the material behind the wave front). Using these methods in the pressure range from 4×10^5 to 5×10^6 atm., the adiabatic curves are obtained for the shock compressibility of iron specimens with various initial densities. The resulting experimental data is used to derive the compressibility curve at absolute zero. The curve is extrapolated to pressures for which the statistical models for an atom are valid. (Authors' abstract) (Abstract in Physics Express, July 1958).

THE DYNAMIC COMPRESSIBILITY OF METALS AT PRESSURES FROM FOUR HUNDRED THOUSAND TO FOUR MILLION ATMOSPHERES
Zhur. Eksper. i Teoret. Fiz. 34:886-93, No. 4, April 1958.

The paper presents a method for determining pressures and densities under conditions of shock compression. The method is based on measuring the propagation velocities for high-power shock waves. The method was used to measure the dynamic compressibility of copper, zinc, silver, cadmium, tin, gold, lead and bismuth in the pressure range 4×10^5 to 4×10^6 atm. The highest degrees of compression (2.26 and 2.28 times) were observed in zinc and bismuth (i.e., for elements with large atomic volumes). The highest absolute density (32.7 g/cm^3) was registered for gold. (Abstract in Physics Express, July 1958).

SHOCK WAVES IN AIR PRODUCED BY WAVES IN A PLATE
Journal of Applied Physics
1955, Vol. 26, pp. 1173-1175.

A shadowgraphic technique has been used to measure surface motion of a series of steel plates while they deform under impact caused by 1/2-in. diameter steel cylinders fired into their back surfaces at about 2800 ft/sec. The strength of the air shock produced when an initial longitudinal wave in a plate strikes the free surface of the plate has been inferred from the measured shock wave velocity in the air. The shock strength has been related to particle velocity of the surface of the plate. The results are compared to previous work involving contact explosions of small charges on plates. STUDIES OF PLASTIC DEFORMATION BY THE PHOTOPLASTIC METHOD
Proceedings Sixth Japanese National Congress of Applied Mechanics, University of Kyoto, Japan, October 1956, pp. 137-140.

A proposal is made to use celluloid to represent an elastoplastic material such as a non-strain-hardening metal, and to determine stress and strain patterns in the plastic range by photoelastic techniques. The few simple examples tested indicate that not only can the plastic stress and strain distribution be determined but also the residual stress pattern after unloading can

be found. Although the time for a complete test is relatively long, the method shows considerable promise for at least qualitative studies of elasto-plastic materials in the plastic range.

2040 Bayoumi S E A and Frankl E K
FUNDAMENTAL RELATIONS IN PHOTOPLASTICITY
British Journal of Applied Physics
October 1953, Vol. 4, pp. 306-310.

A fundamental procedure for photoplastic investigations is proposed. This consists of taking two fringe photographs of the same model, one under load, the second immediately after removal of load. The difference between fringe counts at corresponding points gives the stress difference which in elastic problems is derived from a single photograph. (From authors' summary)

CRITICAL CONSIDERATIONS OF THE DYNAMIC RESISTANCE OF A PLATE CONSISTING OF SEVERAL LAYERS, STRESSED BY IMPACT (German)
Zeitschrift für Angewandte Mathematik and Mechanik, Berlin
May 1949, Vol. 29, pp. 157-159.

The author considers two cases of impact stress in a plate consisting of several layers. _____. The author investigates the question of whether it is of advantage to divide the plate into several layers in order to reduce the impact force, decrease the deceleration of the point of impact and thereby decrease the shear stress around the impact center_____ (Abstract as it appears in Applied Mechanics Review).

THE FORMATION OF CRATER'S BY HIGH SPEED PARTICLES
Meteoritics
1953, Vol. 1, No. 1, pp. 11-27.

This article is a study of the craters formed by high-speed particles (>10, 000 ft/sec). The theories of Öpik are compared to the theory that has been used for lower velocities (volume of crater proportional to kinetic energy). Experimental results are shown.

Problem is well discussed.

AN EFFECT PRODUCED BY OBLIQUE IMPACT OF A CYLINDER ON A THIN TARGET
Letter in Journal of Applied Physics
1954, Vol 25, pp. 675-676.

Letter to the editor describes a phenomenon observed when a circular steel cylinder is fired at ordnance velocities at thin lead targets (0. 005 - 0. 010 in).

If a critical angle of incidence of the projectile on the target is exceeded the front surface of the cylinder is marked by a series of ridges. Photographs are shown of the phenomenon.

SURFACE ENERGY, A MODE FOR ENERGY ABSORPTION DURING IMPACT
American Journal of Physics
1953, Vol. 21, pp. 305-307.

The role that pulverization of the target material may play in absorbing the energy of an impacting missile is discussed. The energy absorbed depends upon the area of the new surfaces formed. Correlation is made to impact of meteorites.

3030 Krafft J M
SURFACE FRICTION IN BALLISTIC PENETRATION
Journal of Applied Physics
1955, Vol. 26, pp 1248-1254.

The frictional adhesion between projectile and target during a ballistic penetration has been measured with a torsion-type Hopkinson bar. The apparatus allows measurement of the torsional adhesion of a spinning projectile during target penetration. By assuming the friction resisting rotation to be equal to that resisting axial penetration, the energy loss due to friction was computed. The results show that the torque time pattern during penetration of a "mechanically" clean projectile can be predicted with the assumption of a frictional energy loss just sufficient to keep the sliding surfaces at the melting temperature of the metal. Metallographic analysis of the target metal at the projectile interface gives a further indication of a molten interface. In these tests, sliding friction accounts for about 3 per cent of the striking energy of the projectile common surface contaminants, not necessarily special lubricants, reduce this loss to less than 1 per cent. (Author's abstract)

AN APPROXIMATE THEORY OF ARMOR PENETRATION
Journal of Applied Physics
1955, Vol. 26, pp. 80-82.

The problem of armor penetration of thin plates is considered from a quasi-dynamical approach. Equations are derived for the energy dissipation due to plastic deformation and for heating of the projectile target interface. Both the conical and the ogival head are considered in the application of the general equations. (Author's abstract)

ELASTIC AND PLASTIC BEHAVIOR IN SIMPLE TARGET-PROJECTILE SYSTEMS
NAVORD Report 5593.

The dynamic interaction of steel projectiles striking aluminum alloy plates at normal incidence has been investigated for geometrically simple projectiles. Observations on the penetration craters formed by flat-nose projectiles and certain idealized stress wave considerations lead to a theory of cavity formation. This can be formulated quantitatively as the relationship of the depth of penetration to (1) impact velocity, (2) certain functions of the characteristic impedances of the target and projectile materials, and (3) an empirically determined dynamic elastic limit. This theory agrees with measurements for small projectiles traveling at velocities between 300 and 850 meters/sec. Velocity ranges of dominantly elastic and dominantly plastic target behavior can be identified. (Author's abstract)

MEASUREMENT OF THE DYNAMIC STRENGTH OF PLASTIC MATERIALS (German)
Zeitschrift für Angewandte Physik
1953, Vol. 5, pp. 1-5.

Starting from theoretical considerations, the importance of experimental conditions in determining the influence

of strain rate on the mechanical properties of materials is pointed out. Some interesting and hitherto unpublished experimental results, obtained by the author by means of an electromagnetic apparatus in which copper wires were loaded by a brief, strong current impulse, are briefly discussed. The effects of the propagation of plastic waves at high-test strain rates (with strain hardening) and of the length of test bar on accuracy of measurement, are considered in this paper.

STRESS-STRAIN CHARACTERISTICS OF MATERIALS AT HIGH STRAIN RATE, PART I
Structural Mechanics Research Lab., The University of Texas.

A photoelectric method for measuring displacements during high-velocity impacts is described. The theory of the system is discussed in detail and a prototype system which was built and tested is described. The performance of the prototype system is evaluated by comparing the results which it gives with results obtained by other methods of measurement. The system was found capable of a resolution of at least .01 inch. (Author's abstract)

THE DYNAMIC PROPERTIES OF MATERIALS UNDER IMPACT
Theoretical Analysis of Scabbing in Materials, Interim Technical Report No. 6, OOR Project No. TB2-0001 (1253) Pennsylvania State University.

The stress-strain curve of a material for dynamic loads is chosen as the basic dynamic property of the material. The importance of strain-rate and other factors affecting it are discussed and some historical remarks presented. Then the present techniques of dynamic testing are discussed. Some semi-analytic approaches to estimate the theoretical relationships are given. After this some qualitative estimates of the nature of behavior of stress-strain curves are presented. In order to be able to study the general behavior of a material under dynamic loads, the necessity of experiments with controlled strain rates is pointed out and design of some experiments of this kind is given. AN OPTICAL PROBE FOR ACCURATELY MEASURING DISPLACEMENTS OF A REFLECTING SURFACE
Journal of Scientific Instruments
1957, Vol. 34, pp. 349-352.

The probe described is capable of accurately measuring the displacement of a plane reflecting surface along its

normal without making mechanical contact with it. The image of an illuminated grating of special construction is formed on the surface to be observed, and the light reflected from this surface then forms an image of equal size on a second, exactly similar, grating. The disposition of the second image relative to the second grating depends upon the position of the probe relative to the plane surface_____.

Displacements may be measured with a standard deviation of 2.8 x 10^{-5} in. Device is apparently for static deflections but appears to have promise for dynamic conditions.

MEASUREMENT OF SMALL DISPLACEMENTS OF A PLANE SURFACE WITH A SEMI-VIRTUAL SLIT MODULATOR (French)
Journal de Physique et le Radium, Paris
June 1956, Vol. 17, No. 6, p. 29.

This method is suitable for measuring the displacement of a polished or plated surface. A metal plate such as a razor blade is mounted parallel to and about 0.01 mm away from the surface observation of the slit at grazing incidence shows a real and a virtual (reflected) edge. Variations in the magnitude of this "semi-virtual slit" are used to modulate a beam of light falling on a photocell for recording static or dynamic displacements of the surface.

APPARATUS FOR THE MEASUREMENT OF TIME OF IMPACT
British Journal of Applied Physics
1956, Vol. 7, pp. 227-228.

An apparatus is described for measuring the time of impact of a ball impacting on a plane surface. A direct connection to the ball is not necessary. The plane surface forms one surface of a capacitor. The other capacitor electrode is a ring at about 5 mm above the plane surface. The ball drops through the ring which changes the capacitance. While the ball is in contact with the surface, the capacitance is unchanged and therefore a measure of the time of impact.

RESPONSE SPECTRA BY MEANS OF OSCILLOGRAPH GALVANOMETERS
Journal of the Acoustical Society of America
1957, Vol. 29, pp. 1110-1115.

A response spectrum (shock spectrum) is the response of a series of a single-degree-of-freedom systems of given damping to a shock or vibratory motion, as a function of the frequencies of the simple systems. An oscillographic galvanometer is a single-degree-of-freedom system having a rotational response to an exciting current. If the exciting current is made proportional to the amplitude of the motion, the response of the galvanometer to the current will be proportional to that of a single-degree-of-freedom system to the motion, provided their natural frequencies and damping properties are the same. A commercial galvanometer-type oscillograph has been obtained having twelve undamped galvanometer elements with natural frequencies in the range between 10 and 2500 cps. Damping by electrical means, has been made adjustable between about 3 and 50% of critical. Associated circuitry have been constructed so that electrical playback of recordings of shock and vibratory motions can be conveniently analyzed. Calibration techniques are described and examples are given for analysis of simple and complex shock motions. (Authors' abstract)

AN EXPERIMENTAL INVESTIGATION OF BEAM STRESSES PRODUCED BY OBLIQUE IMPACT OF A STEEL SPHERE
Journal of Applied Mechanics, Trans. ASME
1956, Vol. 78, pp. 606-611.

An experimental investigation designed to study the phenomena incident to the oblique collision of 1/2-inch-diameter steel spheres with mild-steel and annealed drill-rod beams at oblique angles of incidence has been undertaken. Initial ball velocities ranged from 30 ft/sec to 150 ft/sec, beam sizes varied from 1/4 in. x 1/4 in. to 3/4 in. x 3/4 in., angles of incidence were chosen from 85 deg to normal incidence, and simply supported, clamped, and free beams were employed. Information is reported concerning the values of maximum bending stress at various positions along the beam as function of the angle of incidence and as a function of beam size for various angles of incidence. The progressive dispersion of the initial transient has been examined in detail. The effect of end supports, effective beam length, and repetitive shots into the same hole upon stress are described.

KINEMATIC PHENOMENA OBSERVED DURING THE OBLIQUE IMPACT OF A SPHERE ON A BEAM
Journal of Applied Mechanics, Trans. ASME
1956, Vol. 78, pp. 612-616.

Experimental data relating to the kinetics of oblique impact of a 1/2-inch-diameter steel sphere upon steel beams at initial velocities ranging from 30 to 150 fps are presented. The variation of beam deflection, contact duration, trajectory of the sphere, and contour topography with angle of incidence, beam size, and initial velocity have been determined and the velocity of propagation of several waves has been ascertained.

PLASTIC DEFORMATION OF SEMI-INFINITE BEAMS UNDER TRANSVERSE IMPACT LOADING AT THE FREE END
Journal of Applied Mechanics, Trans. ASME
1956, Vol. 78, pp. 239-243.

The object of this paper is to consider the plastic deformation of the semi-infinite beams subject to dynamic transverse loading at the free end. The type of loading considered is that of a constant bending moment, together with a transverse force the magnitude of which is inversely proportional to the square root of time. Part 1 of the paper consists of a plastic-rigid analysis of the problem, based on the plastic-rigid analysis of infinite beams under transverse, constant velocity, impact loading developed by the author. Part 2 of the paper consists of an elastic-plastic solution of the problem, based on a theoretical analysis of the plastic deformation of infinite beams subject to transverse, constant-velocity impact loading developed by H. F. Bohenblust. Specific problems are considered for which the deflection solutions obtained by elastic ideally plastic and rigid ideally plastic analyses are compared. (Author's abstract)

IMPULSIVE LOADING ON ELASTIC-PLASTIC BEAMS
Journal of Applied Mechanics, Trans. ASME
1956, Vol. 78, pp. 515-521.

A simply supported uniform beam of ductile material, subjected to impulsive loading such that the initial velocity is a half-sine wave, is considered in this paper. The elastic and elastic-plastic motions are discussed under the assumption that plastic flow is confined to one cross section, and the final deformations are compared with those computed from an analysis which neglects all elastic deformations. The purpose of the work is to provide further information which may help in estimating the range of validity of the latter ("rigid-plastic") type of analysis. (Authors' abstract)

IMPACT WITH FINITE ACCELERATION TIME ON ELASTIC AND ELASTIC-PLASTIC BEAMS
Journal of Applied Mechanics, Trans. ASME
1956, Vol. 78, pp. 411-415.

The purpose of the work described in this paper was to provide information on the elastic and plastic deformation of steel beams subjected to transverse impact. The particular impact problem treated was chosen to correspond to conditions in tests in which a beam initially at rest is struck by a massive hammer, so that a specified change of velocity is imposed at a certain cross section in a small time interval. In the present analysis the initial elastic and subsequent elastic-plastic motions were obtained by methods similar to those used by Bleich and Salvadori (3). As in (3), it is assumed that plastic deformation occurs only at a single stationary plastic hinge (in this case at the struck cross section). Results obtained are compared with those of a "rigid-plastic" solution of the same problem, in which plasticity conditions are correctly taken into account but elastic vibrations are not included.

DYNAMIC RESPONSE OF THIN BEAMS TO AIR BLAST
Ballistic Research Laboratories, Report No. 787.

This paper presents a comparison of the theoretically predicted and observed elastic responses of thin simply supported beams and of cantilever beams to air-blast loading. The theoretical responses are predicted from the linear "small-deflection" beam theory and compared to motions observed with a high-speed motion picture camera. The agreement of observed deflections with predicted ones is adequate for the thicker beams where the deflections were small, but inadequate for the thinner beams where the deflections were large. (Authors' abstract)

4033 Harris J I
LARGE DEFLECTIONS OF NON-UNIFORM ELASTIC BEAMS SUBJECTED TO TRANSIENT LOADS
Ballistic Research Laboratories, APG, Memo Report No. 1105, October 1957.

This report presents a method of solving the non-linear equation for large flexing motions of thin beams subjected to transient loads. The small deflection linearized equation is solved by successive approximation, and this solution is extended to large deflections by a perturbation scheme. The solution shows that the apparent dynamic load on any normal mode is not equal to the applied load. Because no experimental results on non-uniform beams are available, large deflections for a uniform cantilevered beam are predicted from the general solution and compared with experimental results. Agreement between experimental results and the general solution is better than that between experiment and the predictions from the solution of the linearized equations. (Author's abstract)

4034 Baker W E and Allen F J
THE DAMPING OF TRANSVERSE VIBRATIONS OF THIN BEAMS IN AIR
Ballistic Research Laboratories, APG, BRL Report No. 1033 October 1957.

A non-linear partial differential equation describing the free transverse vibration of thin beams in air is formulated. The equation accounts for two types of force on the beam caused by its motion through the air and for the force caused by internal friction of the beam material, in addition to the usual elastic and inertia forces. An approximate solution to the equation is obtained by a perturbation method.

A series of experiments were conducted at large initial vibration amplitude to corroborate the theory, which predicts that "pressure drag" air damping is proportional to amplitude and that "viscous drag" air damping and internal damping are independent of amplitude. The dependence of pressure drag damping on air pressure is also predicted. The experimental results show reasonable agreement with the theory; however, the importance of viscous air drag damping relative to that of internal friction cannot be determined. (Authors' abstract)

4035 Allen F J
AN ELASTIC-PLASTIC THEORY OF THE RESPONSE OF CANTILEVERS TO AIR BLAST LOADING
Ballistic Research Laboratories, Memorandum Report No. 886.

An elastic-plastic theory of the response of cantilevers loaded by air blast waves is proposed and the predictions obtained from it are compared to experimental results. The theory is capable of providing estimates for the types of beams considered; it is expected to furnish more precise estimates for certain other beams of practical interest.

A method is developed by means of which a high speed digital computing machine can rapidly and accurately predict dynamic elastic strains, moments, and deflections in certain structures. (Author's abstract)

4036 Allen F J and Rally F
A PLASTIC-RIGID THEORY OF THE RESPONSE OF BEAMS TO AIR BLAST LOADING
Ballistic Research Laboratories, Memorandum Report No. 811.

This report presents a "plastic-rigid" theory of cantilever and simply-supported beams subjected to air blast loading. The equations of motion are derived and the theoretical deformations found. Theoretically predicted permanent deformations are compared to experimentally determined permanent deformations of thin rectangular cross-section metal beams subjected to air blast load. The theory predicts correctly the occurrence of localized regions of plastic deformation, but does not accurately predict the amount of this deformation. However, the results suggest a modification of the theory which is expected to be in better agreement with experiment. Authors' abstract)

4037 Plass H J
SOME SOLUTIONS OF THE TIMOSHENKO BEAM EQUATION FOR SHORT PULSE-TYPE LOADING
Journal of Applied Mechanics, Trans. ASME
1958 Vol. 80, pp. 379-385.

A collection of solutions to the Timoshenko beam equation is presented. Various types of support conditions and impact conditions are included. In every case the impact is assumed to be a pulse in the form of a half-sine wave. The results were found numerically, using the method of characteristics, except for one case, which was done in addition by the Laplace transform method, for check purposes. Agreement with experiment is good except for a pulse of duration comparable to the time required for the bending-type wave to travel a distance of one diameter. Discussion is included of the differences among the various cases studied. (Author's abstract)

4038 Abramson H N
FLEXURAL WAVES IN ELASTIC BEAMS OF CIRCULAR CROSS SECTION
Journal of the Acoustical Society of America
1957, Vol. 29, pp. 42-46.

The exact equations of elasticity are employed in an investigation of the flexural vibrations of a solid circular cylinder. Contrary to previous work, it is shown that the phase-velocity-wavelength relation has an infinity of branches, thus overcoming objections, on physical grounds, which have been made to the earlier work. The three lowest branches of this dispersion relation are calculated, and these are used to study the rate of energy transmission in terms of group velocity. (Author's abstract)

SHOCK SPECTRUM AS A CRITERION OF SEVERITY OF SHOCK IMPULSES
Journal of the Acoustical Society of America
1957, Vol. 29, Part 1, pp. 596-602.

> Shock impulses have not as yet yielded to any practical method of spectral analysis that would permit convenient exact calculation of all the peak internal responses of hardware subject to such accelerations, and also permit comparison of shock severities by inspection. The shock spectrum with a few supplementary techniques, provides adequate insight into the responses of a one degree of freedom resonator. As an indication of the responses of a system with several coupled degrees of freedom, a second-order shock spectrum is defined. An oscillatory constituent of the spectrum is also defined in such a way as to be applicable to any order of spectrum. Investigation of these two concepts leads to the conclusion that if the first-order shock spectrum technique is to be used as a basis for comparison of the severity of a laboratory test shock with that of a service shock, spectra should be plotted for both positive and negative directions. Moreover, when feasible, such spectra should ordinarily be plotted as distinct curves for the intervals during and after the test shock, and the oscillatory constituent for the interval during the shock should be estimated.

A METHOD OF STEPWISE INTEGRATION IN PROBLEMS OF IMPACT BUCKLING
Journal of Applied Mechanics, Trans. ASME
1956, Vol. 78, p. 291.

The equations for the dynamic buckling of an axially impacted column are discussed. A method is presented for the calculation of approximate load and deflection variations in problems of high-velocity impact. The method may be extended for cases wherein the stresses exceed the elastic limit. Results of calculations are presented for two cases. In one of these, agreement with a previous exact solution is found to be good. (Author's abstract)

5011 Yoh-Han Pao
EXTENSION OF THE HERTZ THEORY OF IMPACT TO THE VISCO-ELASTIC CASE
Journal of Applied Physics
1955, Vol. 26, pp. 1083-1088.

The problem considered is that of two bodies coming into normal contact over smooth curved surfaces. The initial relative velocity and the total kinetic energy involved is low. Contact is, however, confined to such small volumes of the objects involved that very high concentrations of energies are obtained at those places. The rates of application of stress are correspondingly high. The Hertz solution to this type of problem provides a useful approximation in the case of elastic objects.

In the present treatment one of the impinging bodies is of viscoelastic material. Two viscoelastic bodies may also be treated if they are of the same material. The Laplace transform method is used to obtain the visco-elastic expression for the force developed between the two surfaces. This expression is then applied to the impact case. The expression can also be applied to other truly static cases; e.g., contact between gear tooth surfaces.

The results are of technological interest, since it is not possible to say if a plastic is suitable for a certain category of impact applications, unless the rates of straining or stressing obtained in those applications can be estimated. (Author's abstract)

PROPAGATION OF A SUDDEN ROTATIONAL DISTURBANCE IN AN ELASTIC PLATE IN PLANE STRESS
Journal of Applied Mechanics, Trans. ASME
1956, Vol. 78, pp. 284-286.

Detailed results are found for two plane-stress problems of an elastic plate with a hole from which a symmetrical distrubance is propagated. In the first a uniform shear stress is suddenly applied and maintained at the hole. In the second a uniform (rotary) velocity is suddenly applied and maintained. The subsequent motion is entirely rotary and involves shear stress only. The problems are mathematically analogous to those of symmetrical pressure and radial velocity at the hole, already solved by Kromm, and his analysis is followed. The existence of a similar analogy in the statistical cases is well known. (Author's abstract)

CONDITION OF HIGH-VELOCITY DUCTILE FRACTURE
Journal of Applied Physics
1955, Vol. 26, pp. 900-902.

The Griffith energy criterion, $dW = -dU$ (dW = crack propagation work, $-dU$ = released elastic energy), cannot be applied to essentially ductile fractures. In particular, it does not represent the condition of rapid ductile fracture propelled by the elastic energy of the specimen. The condition of such fractures is $d^2W/dx^2 = -d^2U/dx^2$, where x is the plastic extension accompanying the propagation of the crack.

ELASTIC RESPONSE OF SIMPLE STRUCTURES TO PULSE LOADING
Ballistic Research Laboratories, Memorandum Report No. 525.

This paper deals with the elastic response of some simple structures subjected to a pulse loading. The structures considered are the mass on a spring, the simply supported beam, the cantilever, the circular membrane, and the clamped circular plate. The loading considered is that of a triangular pulse of pressure uniformly distributed over the area of the structural normal to the direction of motion. The pressure jumps to its peak value instantaneously and falls off linearly with increase in time, reaching

the value zero at the end of the pulse. Initially the structures are at rest and have no displacement.

The case of the simply supported beam is treated in some detail in order to illustrate the method of solution. In the other cases only the conditions necessary to specify the problem and the corresponding solutions for the deflection and strain as functions of the spatial argument and time are given. A numerical example is worked out for the simply supported beam, and the curves of deflection-time and strain-time are given for both during and after the pulse. A method is developed whereby the solutions for the triangular pulse may be modified to give directly the response of the structures to a general pressure-time loading. (Author's abstract)

THE RESPONSE OF ELASTIC SPHERICAL SHELLS TO SPHERICALLY SYMMETRIC INTERNAL BLAST LOADING
Ballistic Research Laboratories, APG, BRLM Report No. 1113, August 1957.

This report presents the results of an analytical study of the reaction of an idealized nuclear reactor containment shell to internal transient loading which could be caused by reactor runaway.

The containment shell is assumed to be an elastic hollow sphere, and the transient loading is assumed spherically symmetric. A general theory of the response, valid for shells of any thickness, is developed. The theory is approximated for thin shells, and compared with experiment. The experiments corroborate the theoretical predictions. (Authors' abstract)

SHORT-TIME IMPULSES PRODUCED BY LONGITUDINAL IMPACT
Paper presented at Spring Meeting of the Society for Experimental Stress Analysis, held May 14-16, 1958.

A program for the precise measurement of pulses in narrow rectangular bars generated by longitudinal impact of a 1/2-inch diameter steel ball was executed. The pulses were detected by means of resistance wire strain gages of various lengths and sandwiched piezoelectric quartz crystals, and were compared to the measured change of momentum of both ball and bar. An initial impact velocity up to 190 ft/sec always yielded permanent dents in the bar at the contact point with a depth small compared to the ball radius. Rise times of the order of 10 microseconds and peak forces of about 9,500 pounds were produced. No significant difference in the pulse shapes was observed from the records of wire-resistance strain gages and crystals,

but gages are considerably more convenient to use and are more universal in application. The impulses for longitudinal and transverse impact under similar geometric conditions appear to be comparable. (Authors' abstract)

HIGH-SPEED FRACTURE IN RUBBER
Journal of Applied Physics
1958, Vol. 29, pp. 1146-1150.

Cinematographic observations have been made of crack propagation under well-defined boundary conditions in rubbers at speeds up to 30 m/sec. The fracture markings showed resemblances to those obtained with metals, plastics, and glass, and could be related directly to the corresponding speed of fracture-propagation. In close analogy with Schardin's observations on glass, a noncrystallizing rubber (GR-S) showed a mode of crack propagation in which the fractured surfaces were visually smooth and the speed was about one quarter of the speed of longitudinal elastic waves. A crystallizing rubber (natural rubber) did not show this mode of propagation under the present test conditions. It is suggested that the modes of solid fracture can be usefully classified in three categories: (i) slow propagation, generally with smooth surfaces, obtained by careful control of the boundary conditions; (ii) propagation at intermediate rates with rough surfaces, involving correspondingly greater energy consumption; and (iii) fast propagation with smooth surfaces, the rate of propagation being limited by the speed of elastic waves in the material in accord with Mott's theory.
